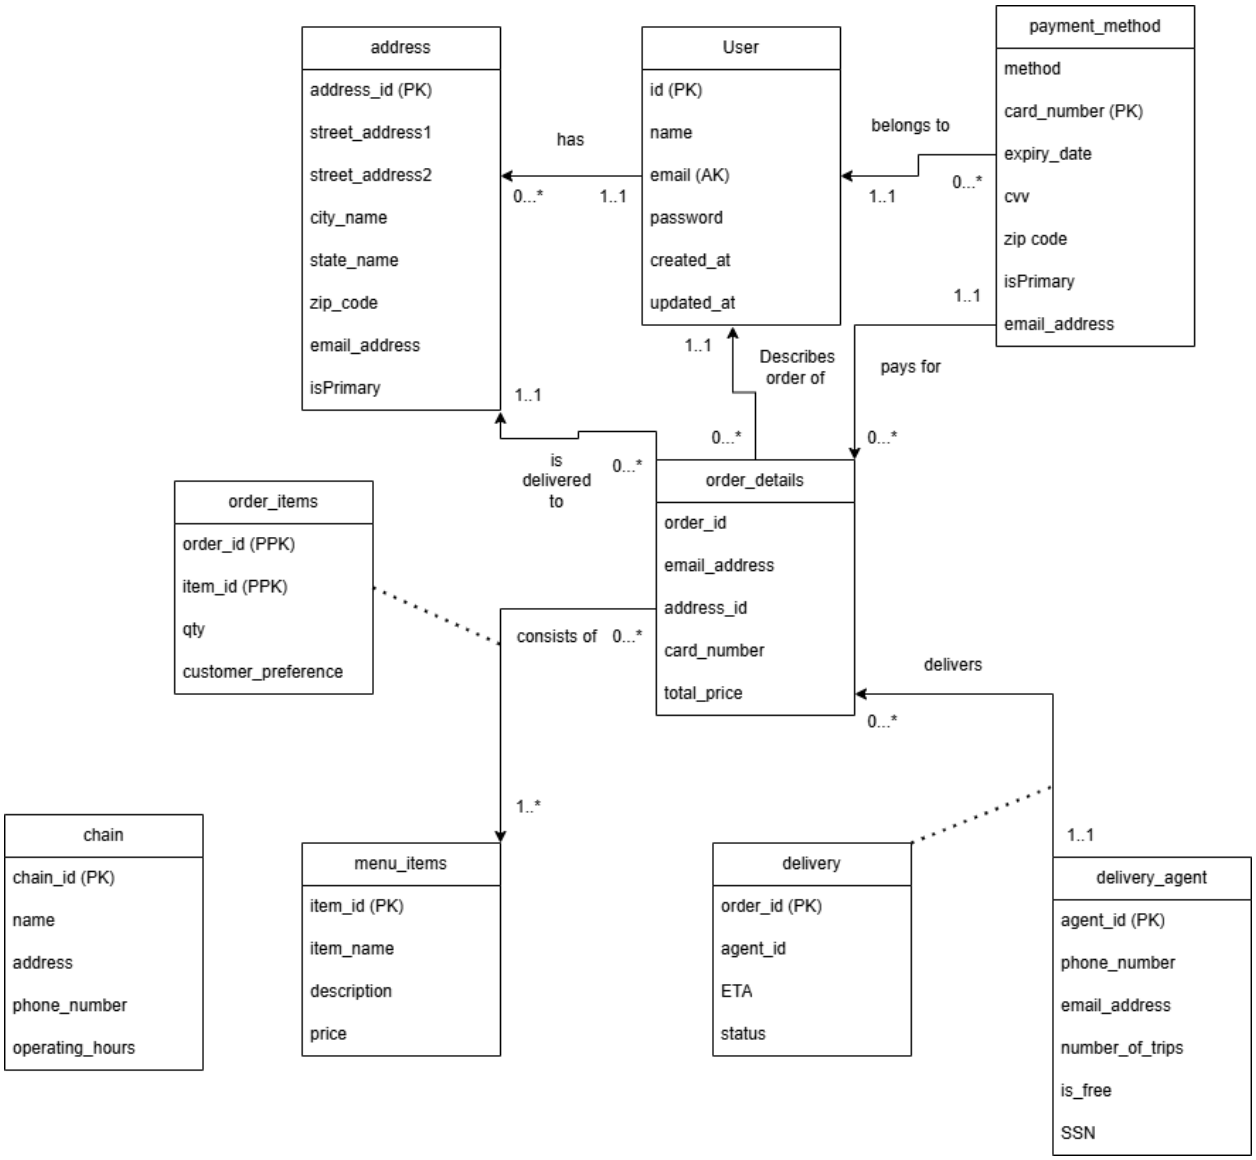
1. **README**: **<u>Food Delivery App.</u> - <u>Nishant Suresh & Shreyas Manoti</u>.**

1. We have created a working Full Stack website for this project. We have created this Full Stack Project. (React for Frontend and Node Express Js for Backend) and MySQL for the Database.
2. There will be 2 folders named food-delivery-fe and food-delivery-be which will contain the files for frontend and backend respectively.
3. We hope the dump of our sql db would be imported and loaded into MySQL Workbench.
4. For Testing our application do the following:
    a. For food-delivery-be (backend code) just unzip the folder and open the folder in another instance of any code editor (lets say vscode).
    b. If you don't have nodejs installed please install nodejs from https://nodejs.org/en/download.
    c. In the terminal please do a "npm install" command to install the node_modules(which we will have deleted to reduce the size of the file).
    d. Before doing the "npm run server" command please go into the .env file in the root and fill in the details such as DB_HOST=localhost, DB_USER, DB_PASSWORD, DB_NAME=food_delivery, PORT=3000, JWTSECRET="securekey"
    e. Please enter the tester's db_user(by default root) and password in DB_PASSWORD.
    f. After the node packages are installed type in the command "npm run start" or "npm run server" to start the node js application which will start in port 3000. (Can be accessed at localhost:3000 locally - Dont have to access this as this is just a node server - just let it run in the background).
    g. For food-delivery-fe just unzip the folder and open the folder in any code editor (lets say vscode).
    h. In the terminal please do a "npm install" command to install the node_modules(which we will have deleted to reduce the size of the file).
    i. After the node packages are installed type in the command "npm run dev" to start the react app which will start in port 5173. (Can be accessed at localhost:5173 locally).
    j. This would setup the frontend up and running in the local machine.
    k. At this point you'd be able to use the application.
    l. Demo would be attached in a video format.

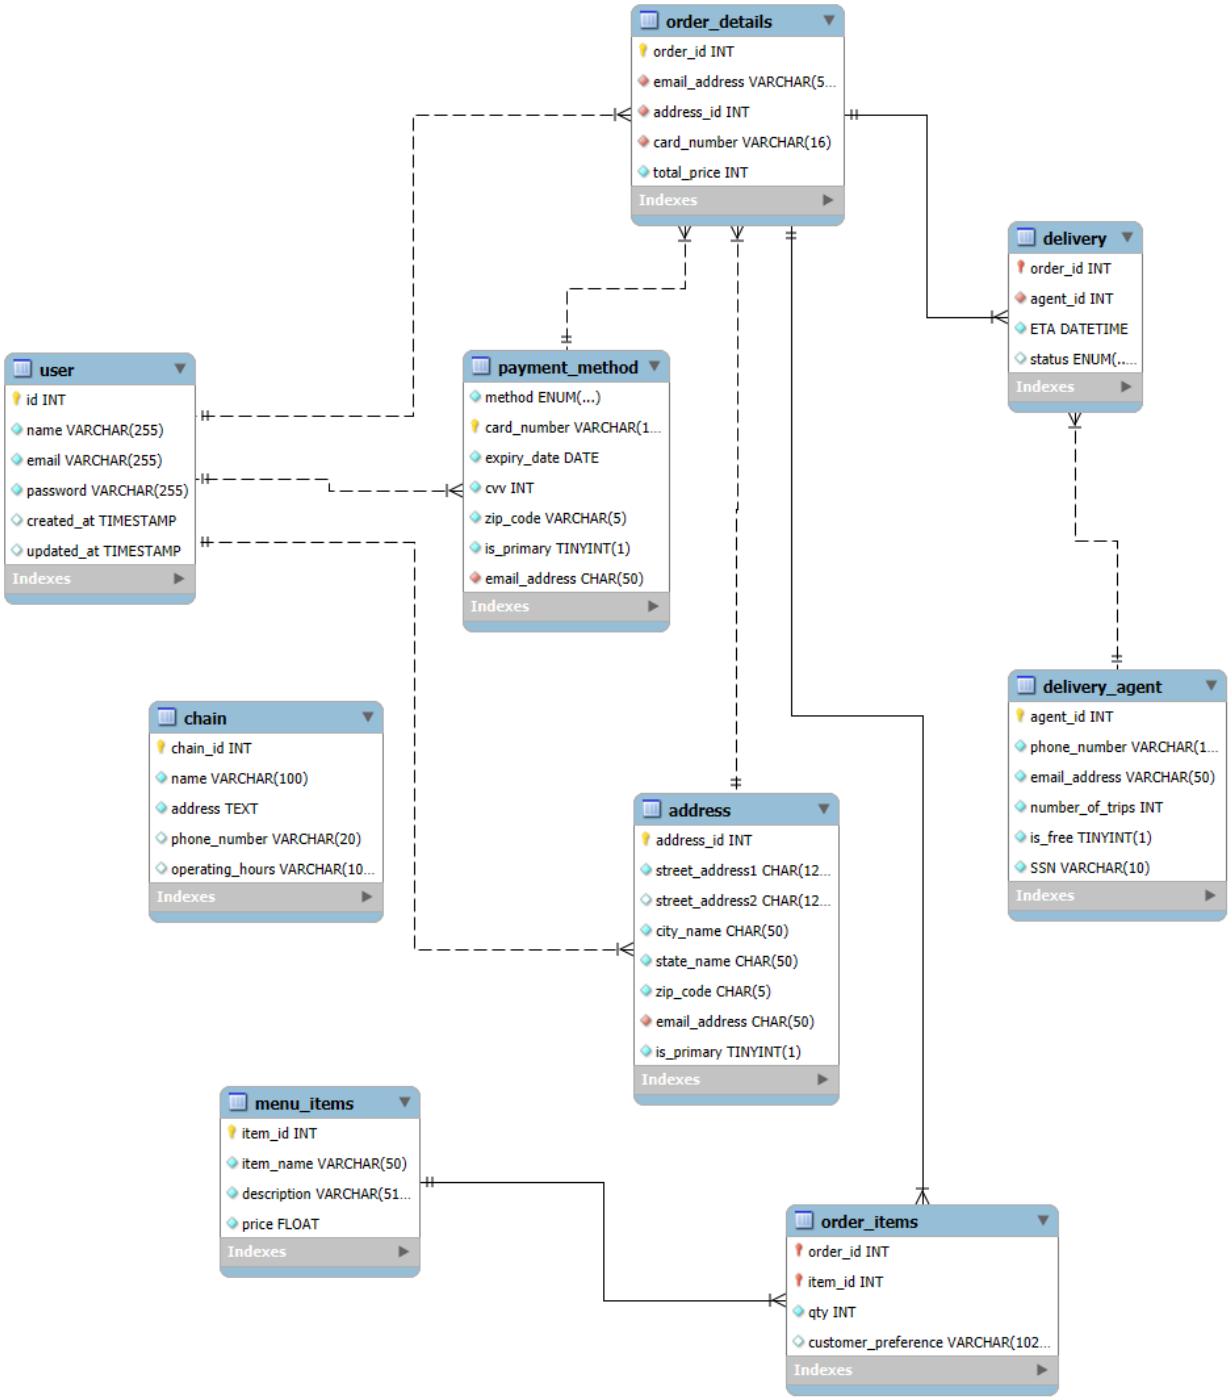
2. **TECHNICAL SPECIFICATIONS**:

1. Used React js for Frontend, Nodejs & ExpressJs for backend and MySQL for Database.
2. Host language is Javascript.
3. Other Softwares used: MySQL Workbench, Postman.

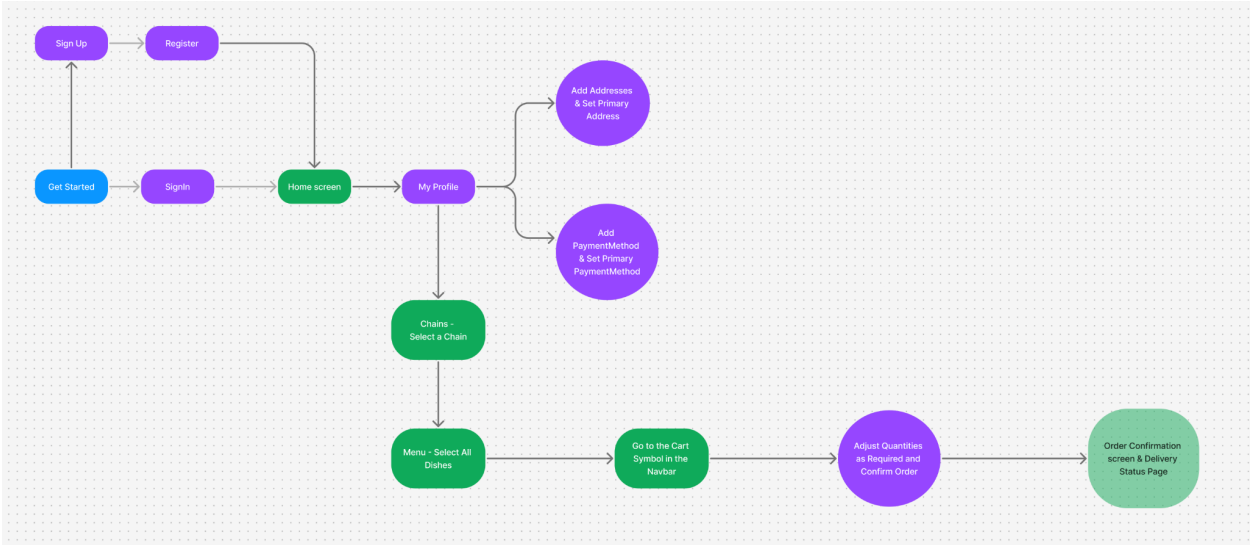
3. **UML DIAGRAM**



4 . LOGICAL DESIGN



5. FINAL USER FLOW



1. As mentioned in the README, only the setup of the project requires some commands as mentioned in the README. Other than that the User Interface is a simple Website that is easy to use and intuitive.
2. The detailed explanation of the data flow in the application is demonstrated in the Demo Video.

6. Lessons Learned

1. Technical expertise gained - Refined and gained significant knowledge in integrating frontend with backend and modifying apis to get the appropriate knowledge.
2. Insights, time management insights, data domain insights etc - Time management was crucial in this project as full stack application got us bogged down in creating different pages and fixing the bugs once the backend was connected and the data was moving through the 2 application layers.
3. Realized or contemplated alternative design / approaches to the project
4. Document any code not working in this section

7. Future work

1. Planned uses of the database: We aim to develop this backend further into a full-fledged real-time db that can be deployed in the real world to track multiple delivery-agents, cooking-time and predict delivery-time based off of real-time traffic data using google maps data etc.
2. Potential areas for added functionality:- Potential areas for added functionality is like mentioned above real time tracking of the delivery-agent, a more accurately predicted delivery estimate based off of real-time traffic data.
